## **Publication Notes**

The short version of this technical report is accepted to the conference IJCAR 2004 and is copyrighted by Springer-Verlag.

## **Acknowledgements**

The authors would like to thank Konstantin Korovin for reading the draft of the paper and giving valuable remarks. The first author is supported by the International Max Planck Research School for computer science (IMPRS).

## **Abstract**

We show how well-known refinements of ordered resolution, in particular redundancy elimination and ordering constraints in combination with a selection function, can be used to obtain a decision procedure for the guarded fragment with transitive guards. Another contribution of the paper is a special scheme notation, that allows to describe saturation strategies and show their correctness in a concise form.

The report is an extended version of the paper (Kazakov & de Nivelle 2004).

# 1 Introduction

The *guarded fragment*  $\mathcal{GF}$  of first order logic has been introduced by Andr eka, van Benthem & N emeti (1998) to explain and generalize the good computational properties of modal and temporal logics. This is achieved essentially by restricting quantifications in first order formulae to the following “bounded” forms:  $\forall \bar{x}.[G \rightarrow F]$  and  $\exists \bar{y}.[G \wedge F]$ , where  $G$  should be an atomic formula (so-called *guard*) containing all free variables of  $F$ . The guarded fragment is decidable in 2EXPTIME (Gr adel 1999) and inherits many other nice computational properties from the modal logics like the finite model property, the interpolation property and invariance under an appropriate notion of bisimulation.

Many extensions of the guarded fragment have been found to capture the known formalisms: the *loosely guarded fragment* has been introduced by van Benthem (1997) to capture the until operator in temporal logics; Gr adel & Walukiewicz (1999) have extended the guarded fragment by fixed-point constructors to capture the modal mu-calculus. All these extensions of the guarded fragment, however, cannot express the *transitivity axiom*:  $\forall xyz.(xTy \wedge yTz \rightarrow xTz)$ . Transitivity is important, since it is used to model discrete time (in temporal verification) and ordered structures (in program shape analysis). The question of whether transitivity can be safely integrated into the guarded fragment was answered negatively by Gr adel (1999). He proved that the guarded fragment becomes undecidable as long as transitivity is allowed. This result was later sharpened by Ganzinger, Meyer & Veanes (1999) who showed that even the *two-variable* guarded fragment  $\mathcal{GF}^2$  with transitivity is undecidable. The same paper, however, presents the first restriction of the guarded fragment, where transitivity can be allowed without loss of decidability. In this, so-called *monadic*  $\mathcal{GF}^2$ , binary relations are allowed to occur as guards only. The paper poses two natural questions: **(i)** Does  $\mathcal{GF}$  remain decidable if *transitive* predicates are admitted only as guards? **(ii)** What is the exact complexity of the monadic  $\mathcal{GF}^2$ ? The first question was answered positively in (Szwast & Tendera 2001) where using a heavy model-theoretic construction, it was shown that the *guarded fragment with transitive guards*  $\mathcal{GF}[\mathcal{TG}]$  is decidable in 2EXPTIME. Kieroński (2003) has proved the matching 2EXPTIME lower bound for the *monadic*  $\mathcal{GF}^2$  with transitivity, answering hereby the second question.

A practical disadvantage of procedures based on enumeration of structures, like the one given for  $\mathcal{GF}[\mathcal{TG}]$  in (Szwast & Tendera 2001), is that without further optimizations, those methods exhibit the full worst-case complexity. Resolution-based approach, is a reasonable alternative to model-theoretic procedures, as its goal-oriented nature and numerous refinements

allow to scale well between “easy” and “hard” instances of problems. In this paper we demonstrate the practical power of resolution refinements, such as redundancy elimination and usage of ordering constraints in combination with selection function. We present a first resolution-based decision procedure for  $\mathcal{GF}[\mathcal{TC}]$ . Another aspect that is demonstrated in our paper is the usage of resolution as a specification language for decision procedures. We introduce a special scheme notation that allows to describe resolution strategies in a concise form. This may provide a formal foundation for using resolution for specifying decision procedures and proving their correctness.

## 2 Preliminaries

We shall use a standard notation for first-order logic clause logic. An *expression* is either a term or a literal. A *literal symbol*  $l$  is either  $a$  or  $\neg a$ , where  $a$  is a predicate symbol. An *expression symbol*  $e$  is either a functional symbol  $f$  or a literal symbol  $l$ . We write literals and expressions using literal symbols and expression symbols as follows:  $L = l(t_1, \dots, t_n)$ ,  $E = e(t_1, \dots, t_n)$ . As usual, a clause is a disjunction of literals  $C = L_1 \vee \dots \vee L_n$ . The empty clause is denoted by  $\square$ . We use the shortcuts  $\bowtie$  for conjunction or disjunction and  $\bar{x}$  for some vector of variables.

The *depth of an expression*  $dp(E)$  is recursively defined as follows: **(i)**  $dp(x) := 0$ ; **(ii)**  $dp(e(t_1, \dots, t_n)) := \max\{0, dp(t_1), \dots, dp(t_n)\} + 1$ . The *depth of the clause*  $C = L_1 \vee \dots \vee L_n$  is  $dp(C) := \max\{0, dp(L_1), \dots, dp(L_n)\}$ . The *width of a formula*  $wd(F)$  is the maximal number of free variables in subformulas of  $F$ .

### 2.1 The framework of resolution theorem proving

For describing the decision procedures we use the well-known ordered resolution calculus with selection  $\mathcal{OR}_{Sel}^\succ$  enhanced with additional simplification rules. Our presentation of the calculus is very close to (Bachmair & Ganzinger 2001). The ordered resolution calculus  $\mathcal{OR}_{Sel}^\succ$  is parametrized by an admissible ordering  $\succ$  and a selection function  $Sel$ . A partial ordering  $\succ$  on atoms is *admissible* (for  $\mathcal{OR}_{Sel}^\succ$ ) if **(i)**  $\succ$  is *liftable*:  $A_1 \succ A_2$  implies  $A_1\sigma \succ A_2\sigma$  for any substitution  $\sigma$  and **(ii)**  $\succ$  is a total reduction ordering on ground atoms. Although resolution remains complete for a much wider class of orderings, admissible orderings are better understood and widely used in existing theorem provers. Examples of admissible orderings are the *recursive path ordering with status RPOS* and the *Knuth-Bendix ordering KBO*.

The ordering  $\succ$  is extended on literals by comparing  $L = A$  as the multiset

---

**Figure 1** The inference rules of  $\mathcal{OR}_{Sel}^{\succ}$

---

**Ordered Resolution**

$$\text{OR} : \frac{C \vee \underline{\mathbf{A}}^* \quad D \vee \neg \underline{\mathbf{B}}}{C\sigma \vee D\sigma}$$

where (i)  $\sigma = mgu(A, B)$ , (ii)  $A$  is maximal in  $C \vee \underline{\mathbf{A}}^*$ , (iii)  $\neg B$  is maximal in  $D \vee \neg \underline{\mathbf{B}}$  and (iv) nothing is selected in the premises.

**Ordered Factoring**

$$\text{OF} : \frac{C \vee \underline{\mathbf{A}} \vee \underline{\mathbf{B}}}{C\sigma \vee A\sigma}$$

where (i)  $\sigma = mgu(A, B)$ , (ii)  $A$  is maximal in  $C \vee \underline{\mathbf{A}} \vee \underline{\mathbf{B}}$  and (iii) nothing is selected in  $C$ .

**Ordered Hyper-resolution**

$$\text{HR} : \frac{C_1 \vee \underline{\mathbf{A}}_1 \dots C_n \vee \underline{\mathbf{A}}_n \quad \neg \underline{\mathbf{B}}_1^\# \vee \dots \vee \neg \underline{\mathbf{B}}_n^\# \vee D}{C_n\sigma \vee \dots \vee C_1\sigma \vee D}$$

where (i)  $\sigma = mgu(A_i, B_i)$ , (ii)  $A_i$  are strictly maximal in  $C_i \vee \underline{\mathbf{A}}_i^*$  and (iii)  $\neg B_i$  are all selected literals in  $\neg \underline{\mathbf{B}}_1^\# \vee \dots \vee \neg \underline{\mathbf{B}}_n^\# \vee D$ ,  $1 \leq i \leq n$ .

---

$\{A\}$  and  $L = \neg A$  as the multiset  $\{A, A\}$ . The ordering on clauses is the multiset extension of the ordering on literals. Given a clause  $C$ , we say that a literal  $L \in C$ , is *maximal in  $C$*  if there is no  $L'$  in  $C$ , with  $L' \succ L$ . A *selection function  $Sel$*  assigns a set of negative literal to every clause. These literals are called the *selected literals*. A literal  $L$  is *eligible* in a clause  $C$  if it is either selected:  $L \in Sel(C)$ , or otherwise nothing is selected and  $L$  is maximal in  $C$ .

The ordered resolution calculus  $\mathcal{OR}_{Sel}^{\succ}$  consists of the inference rules that are given on Fig.1. We mark maximal literals in clauses with “star”, selected literals with “dash” and underline the expressions to be unified. The calculus  $\mathcal{OR}_{Sel}^{\succ}$  is refutationally complete for any choice of an admissible ordering  $\succ$  and a selection function  $Sel$ . This means that every saturated set of clauses has a model, or, dually, the empty clause is derivable from every unsatisfiable clause set. Moreover, the calculus is compatible with a general notion of redundancy which allows to make use of additional simplification rules.

A ground clause  $C$  is called *redundant* w.r.t. a set of the ground clauses  $N$  if  $C$  follows from the set  $N_{\prec C}$  of the clauses from  $N$  that are smaller than

$C$ . A non-ground clause  $C$  is redundant w.r.t.  $N$  if every ground instance  $C\sigma$  of  $C$  is redundant w.r.t. the set  $N^{gr}$  of all ground instances of  $N$ . A *ground inference*  $S \vdash C$  from the clause set  $S$  is called *redundant* w.r.t. a clause set  $N$  if its conclusion  $C$  follows from the set  $N_{\prec_{max(S)}^{gr}}$ , where  $max(S)$  is the maximal clause from  $S$ . A non-ground *inference*  $S \vdash C$  is redundant w.r.t.  $N$  if every ground instance  $S\sigma \vdash C\sigma$  of the inference is redundant w.r.t.  $N$ . A clause set  $N$  is *saturated up to redundancy* if the conclusion of every non-redundant w.r.t.  $N$  inference from  $N$  is contained in  $N$ .

**Theorem 2.1 (Bachmair & Ganzinger 2001)** *Let  $N$  be a clause set that is saturated up to redundancy in  $\mathcal{OR}_{Sel}^{\succ}$ . Then  $N$  is satisfiable iff  $N$  does not contain the empty clause.*

For our decision procedures we do not need the full power of redundancy but rather additional simplification rules. A (non-deterministic) inference rule  $S \vdash S_1 \parallel S_2 \cdots \parallel S_k$  producing one of the clause sets  $S_i$  from the clause set  $S$  is called *sound* if every model of  $S$  can be extended to a model for some  $S_i$  with  $1 \leq i \leq k$ . Additionally, if *every* set  $S_i$  makes some clause from  $S$  redundant, the rule is called a *simplification* rule.

Given a set of clauses  $N$ , a theorem prover based on ordered resolution nondeterministically computes a *saturation* of  $N$  by adding conclusions of inference rules to  $N$  and marking<sup>1</sup> redundant clauses as *deleted* so that they do not participate in further inferences. If the process terminates without deriving the empty clause  $\square$ , then a set of the clauses  $\mathcal{OR}_{Sel}^{\succ}(N)$  is computed that is saturated in  $\mathcal{OR}_{Sel}^{\succ}$  up to redundancy. Theorem 2.1 then implies that the clause set  $N$  is satisfiable, since only satisfiability preserving transformations  $N \Rightarrow \cdots \Rightarrow \mathcal{OR}_{Sel}^{\succ}(N)$  were applied to  $N$ . Note that termination of a saturation process is a key issue of using resolution as a decision procedure. If any application of inference rules is *a priori* guaranteed to terminate for a clause set  $N$  then satisfiability of  $N$  can be decided in finite time by enumerating all possible saturations.

In our paper we use the simplification rule from Fig.2. An additional simplification rule will be introduced later, when a certain class of orderings is considered. We indicate redundant premises of rules by enclosing them in double brackets. The simplification rules are applied *eagerly*, that is before any resolution or factoring inference is made. In particular, in the sequel we assume that no clause contain several occurrences of the same literal.

---

<sup>1</sup>Clauses are not removed from the set to avoid repetition of generation/deletion of the same redundant clauses.

---

---

**2.1.1 Constraint clauses.**

The ordered resolution calculus on non-ground level is a directly lifted version of the calculus on the ground level: **(i)** each clause represents the set of its ground instances and **(ii)** whenever an inference is possible from the ground instances of some clauses, there should be a corresponding inference from the clauses themselves, that captures the result of the ground inference. This is due to the fact that  $\mathcal{OR}_{Sel}^{\succ}$  is parametrized with a liftable ordering  $\succ$  and does not use non-liftable conditions in inferences (like, say, in the paramodulation calculus, when paramodulation to a variable is not allowed). Therefore, in fact, any representation for sets of ground clauses can be admitted as long as the condition **(ii)** above holds. In our decision procedure we use *constraint clauses* of the form:  $C \mid R$ , where  $C$  is a (non-ground) clause and  $R$  is a set of *ordering constraints* of the form:  $t \succ s$  or  $t \succeq s$ . Constraint clause  $C \mid R$  represent the set of ground instances  $C\sigma$  of  $C$  such that every constraint in  $R\sigma$  is true. The ordered resolution calculus and all notions of redundancy can be straightforwardly adopted to be used with constraint clauses: instead of considering all substitutions (for determining a maximal literal, or showing redundancy) one should consider only substitutions satisfying the constraints. In particular, one could use different values for selection function for different constraint variants of the same clause.

**2.2 Schemes of expressions and clauses**

To describe resolution-based decision procedures we have to reason about sets of clauses. We introduce a special notation that allows to represent sets of clauses in a compact form. We extend our vocabulary with additional symbols called *signature groups* that represent sets of functional symbols: *function groups*, predicate symbols: *predicate groups* or literal symbols: *literal groups*. We allow to use these symbols in expressions as usual functional and literal symbols and to distinguish them, we use small letters with a “hat”  $\hat{g}$ . For instance, if  $\hat{f}_{all}$  denotes the set of all functional symbols, we

write  $\hat{f}_{all}(t)$  meaning a term of the form  $f(t)$  where  $f \in \hat{f}_{all}$  (the formal definition follows below). We adopt the following notation for referring to arguments of expressions. By writing  $e[!t_1, \dots, !t_n, s_1, \dots, s_m]$  we mean an expression starting with the expression symbol  $e$ , having all arguments  $t_1, \dots, t_n$  and optional arguments  $s_1, \dots, s_m$  (arranged in some way). Formally, the set of *term schemes*, *literal schemes* and *clause schemes* are defined as follows:

$$\begin{aligned}\hat{T}m &::= x \mid \hat{f}(\hat{t}_1, \dots, \hat{t}_n) \mid \hat{f}[!t_1, \dots, !t_n, \hat{s}_1, \dots, \hat{s}_m], \quad n \geq 0, m \geq 0. \\ \hat{L}t &::= \hat{l}(\hat{t}_1, \dots, \hat{t}_n) \mid \hat{l}[!t_1, \dots, !t_n, \hat{s}_1, \dots, \hat{s}_m], \quad n \geq 0, m \geq 0. \\ \hat{C}l &::= \hat{L} \mid !\hat{L} \mid \hat{C}_1 \vee \hat{C}_2.\end{aligned}$$

where  $\hat{f}$  is a functional group,  $\hat{l}$  is a literal group,  $\hat{t}_i, \hat{s}_j$  with  $1 \leq i \leq n$ ,  $1 \leq j \leq m$  are term schemes,  $\hat{L}$  is a literal scheme and  $\hat{C}_1, \hat{C}_2$  are clause schemes. For convenience, we assume that every functional and literal symbol acts as a singleton group consisting of itself, so usual terms and clauses are term schemes and clause schemes as well.

Each term scheme  $\hat{t}$ , literal scheme  $\hat{L}$  and clause scheme  $\hat{C}$  represents a set  $\{\hat{t}\}$ ,  $\{\hat{L}\}$  and  $\{\hat{C}\}$  of terms, literals and clauses respectively, as defined below:

$$\begin{aligned}\{\hat{T}m\}, \{\hat{L}t\} &:= \{x\} : \{x\} &| \\ &\{\hat{g}(\hat{t}_1, \dots, \hat{t}_n)\} : \{g(t_1, \dots, t_n) \mid g \in \hat{g}, t_i \in \{\hat{t}_i\}, 1 \leq i \leq n\} &| \\ \{\hat{g}[!t_1, \dots, !t_n, \hat{s}_1, \dots, \hat{s}_m]\} &: \{g(h_1, \dots, h_k) \mid g \in \hat{g}, \\ &\{h_1, \dots, h_k\} \cap \{\hat{t}_i\} \neq \emptyset, 1 \leq i \leq n, \\ &\{h_1, \dots, h_k\} \subseteq \cup_{i=1}^n \{\hat{t}_i\} \cup_{j=1}^m \{\hat{s}_j\}\}. \\ \{\hat{C}l\} &= \{\hat{L}\} : \{L_1 \vee \dots \vee L_k \mid \mathbf{k} \geq \mathbf{0}, L_i \in \{\hat{L}\}, 1 \leq i \leq k\} | \\ &\{!\hat{L}\} : \{L_1 \vee \dots \vee L_k \mid \mathbf{k} \geq \mathbf{1}, L_i \in \{\hat{L}\}, 1 \leq i \leq k\} | \\ &\{\hat{C}_1 \vee \hat{C}_2\} : \{C_1 \vee C_2 \mid C_1 \in \{\hat{C}_1\}, C_2 \in \{\hat{C}_2\}\}.\end{aligned}$$

We use the shortcuts  $\hat{e}(\cdot, \bar{x}, \cdot)$ ,  $\hat{e}[\cdot, \bar{x}, \cdot]$  and  $\hat{e}[\cdot, !\bar{x}, \cdot]$  where  $\bar{x}$  is a vector  $x_1, \dots, x_n$ , to stand for  $\hat{e}(\cdot, x_1, \dots, x_n, \cdot)$ ,  $\hat{e}[\cdot, x_1, \dots, x_n, \cdot]$  and  $\hat{e}[\cdot, !x_1, \dots, !x_n, \cdot]$  respectively. We write  $\cdot \vee \neg !\hat{A} \vee \cdot$  in clause schemes instead of  $\cdot \vee !\neg \hat{A} \vee \cdot$ , where  $\hat{A}$  is either of the form  $\hat{a}(\cdot)$  or  $\hat{a}[\cdot]$ . In fact we use variable vectors  $\bar{x}$  and functional symbols without “hat”  $f$  as *parameters of clause schemes*. A clause scheme  $\hat{C}(\bar{x}, f, \cdot)$  with parameters  $\bar{x}, f, \cdot$  represents the union  $\{\hat{C}\} := \cup_{\eta} \{C\eta\}$  for all substitutions  $\eta$  of vectors  $x_1, \dots, x_n$  for  $\bar{x}$ , function symbols for  $f$ , etc..

**Example 2.1** Suppose  $\hat{a}$  is a predicate group consisting of all predicate symbols and  $\hat{\alpha} := \{\hat{a}, \neg \hat{a}\}$  is a literal group consisting of all literal symbols. Then the clause scheme  $\hat{C} = \neg !\hat{a}[\bar{x}] \vee \hat{a}[\cdot f(\bar{x}), \bar{x}]$  has two parameters:  $\bar{x}$  and  $f$ . Any clause  $C \in \{\hat{C}\}$  corresponds to some choice of these parameters

$\bar{x} = x_1, \dots, x_n$ ,  $f = f'$ . The clause  $C$  should have a nonempty subset of negative literals containing all variables  $x_1, \dots, x_n$  and no other arguments. Other literals of  $C$  should contain the subterm  $f'(x_1, \dots, x_n)$  as an argument and possibly some variables from  $x_1, \dots, x_n$ . In particular,  $\{\hat{C}\}$  contains the clauses  $\neg a(x, y, x) \vee b(y, f'(x, y))$ ,  $\neg b(x, y) \vee \neg b(y, x)$  and  $\neg p \vee \neg q(c, c)$ , but not the clauses  $\neg a(x, y, x) \vee b(f'(x, y), f'(y, x))$  because the functional subterms are different, or  $\neg b(y, f'(x, y))$  because the clause does not have a guard.  $\diamond$

### 3 Deciding The Guarded Fragment by Resolution

In this section we demonstrate our technique by revisiting a resolution decision procedure for the guarded fragment without equality. The original procedure is due to (de Nivelles & de Rijke 2003). Resolution-based decision procedures (for an overview see Fermüller, Leitsch, Hustadt & Tammet 2001) usually consist of several main steps. First, a clause normal form transformation is applied to a formula of a fragment that produce *initial clauses*. Then a clause set containing the initial clauses is defined, that is shown later to be closed under inferences of the calculus. Decidability and complexity results follow from the fact that the defined clause class contains only finitely many different clauses over a fixed signature.

#### 3.1 Clause normal form translation

In order to describe the transformation to a *clause normal form* (CNF), it is convenient to use the *recursive definition* for the guarded fragment:

$$\mathcal{GF} ::= \mathbf{A} \mid \mathbf{F}_1 \vee \mathbf{F}_2 \mid \mathbf{F}_1 \wedge \mathbf{F}_2 \mid \neg \mathbf{F}_1 \mid \forall \bar{x}.(\mathbf{G} \rightarrow \mathbf{F}_1) \mid \exists \bar{x}.(\mathbf{G} \wedge \mathbf{F}_1).$$

where  $\mathbf{A}$  is an atom,  $\mathbf{F}_i, i = 1, 2$  are guarded formulas, and  $\mathbf{G}$  is an atom called *the guard* containing all free variables of  $\mathbf{F}_1$ . The translation of a guarded formula into CNF is done in two steps. First, the formula is transformed into *negation normal form* (NNF) in the standard way. Guarded formulas in NNF are defined by the following recursive definition:

$$[\mathcal{GF}]^{nnf} ::= (\neg)\mathbf{A} \mid \mathbf{F}_1 \vee \mathbf{F}_2 \mid \mathbf{F}_1 \wedge \mathbf{F}_2 \mid \forall \bar{y}.(\mathbf{G} \rightarrow \mathbf{F}_1) \mid \exists \bar{y}.(\mathbf{G} \wedge \mathbf{F}_1).$$

Second, a so-called *structural transformation* is applied, that decomposes the formula by introducing *definitions* for all of its subformulae. We assume that to each subformula  $\mathbf{F}'$  of  $\mathbf{F}$ , a unique predicate  $P_{\mathbf{F}'} = p_{\mathbf{F}'}(\bar{x})$  is assigned. Each predicate  $P_{\mathbf{F}'}$  has the arity equal to the number of free variables  $\bar{x}$  of  $\mathbf{F}'$ . Using the new predicates, the structural transformation can be defined as

$\exists \bar{x}. P_{\mathbb{F}} \vee [\mathbb{F}]^{st}$ , where  $[\mathbb{F}]^{st}$  is given below. In each row,  $\bar{x}$  are the free variables of  $\mathbb{F}$ .

$$\begin{aligned}
[\mathbb{F}]_g^{st} := [(\neg)\mathbb{A}]_g^{st} &: \forall \bar{x}. (P_{\mathbb{F}} \rightarrow (\neg)\mathbb{A}) && | \neg p_{\mathbb{F}}(\bar{x}) \vee (\neg)a[\bar{x}] \\
[\mathbb{F}_1 \bowtie \mathbb{F}_2]_g^{st} &: \forall \bar{x}. (P_{\mathbb{F}} \rightarrow [P_{\mathbb{F}_1} \bowtie P_{\mathbb{F}_2}]) \wedge [\mathbb{F}_1]_g^{st} \wedge [\mathbb{F}_2]_g^{st} && | \neg p_{\mathbb{F}}(\bar{x}) \vee p_{\mathbb{F}_i}[\bar{x}] [\vee p_{\mathbb{F}_j}[\bar{x}]] \\
[\forall \bar{y}. (\mathbb{G} \rightarrow \mathbb{F}_1)]_g^{st} &: \forall \bar{x}. (P_{\mathbb{F}} \rightarrow \forall \bar{y}. [\mathbb{G} \rightarrow P_{\mathbb{F}_1}]) \wedge [\mathbb{F}_1]_g^{st} && | \neg g[!\bar{x}, !\bar{y}] \vee \neg p_{\mathbb{F}}(\bar{x}) \vee p_{\mathbb{F}_1}[\bar{x}, \bar{y}] \\
[\exists y. \mathbb{F}_1]_g^{st} &: \forall \bar{x}. (P_{\mathbb{F}} \rightarrow \exists y. P_{\mathbb{F}_1}) \wedge [\mathbb{F}_1]_g^{st}. && | \neg p_{\mathbb{F}}(\bar{x}) \vee p_{\mathbb{F}_1}[f(\bar{x}), \bar{x}]
\end{aligned}$$

The transformation unfolds a guarded formula according to its construction and introduces predicates and definitions for its guarded subformulae. A guarded formula  $\mathbb{F}$  in negation normal form is satisfiable whenever  $\exists \bar{x}. P_{\mathbb{F}} \wedge [\mathbb{F}]^{st}$  is: one can extend the model of  $\mathbb{F}$  by interpreting the new predicate symbols according to their definitions. Every recursive call of the transformation contributes to a result with a conjunct describing a definition for an introduced predicate. Performing the usual skolemization and writing the result in a clause form, we obtain the clauses shown to the right of the definition for  $[\mathbb{F}]_g^{st}$ . It is easy to see that the clauses for  $P_{\mathbb{F}} \wedge [\mathbb{F}]_g^{st}$  fall into the set of clauses described by the following clause schemes:

$$\begin{aligned}
1. & l[\hat{c}]; \\
2. & \neg !p[!\bar{x}] \vee l[f(\bar{x}), \bar{x}].
\end{aligned} \tag{G}$$

where the predicate group  $p$  consists of all (initial and introduced) predicate symbols and the literal group  $l$  consists of all literal symbols. Clauses of the form 1 from (G) are shallow clauses containing only constant arguments. The clauses of the form 2 are the so-called *guarded clauses*. Every clause of this form has a non-empty set of negative literals-guards that contain all variables of the clause. Other literals may contain as arguments either variables, or a functional term whose arguments are all variables of the clause. This functional term should be unique for each clause of the form 2 (see also Example 2.1).

### 3.2 Saturation of the clause set

The resolution calculus has two parameters that can be chosen: an admissible ordering and a selection function. These parameters should prevent clauses from growing during the inferences. We will set the ordering and selection function in such a way, that eligible literals would be **(i)** of maximal depth and **(ii)** contain all variables of the clause.

We assume that the ordering  $\succ$  enjoys  $L \succ K$  for  $L \in \{p[!f(\bar{x}), \bar{x}]\}$  and  $K \in \{p[\bar{x}]\}$ , that is, any literal containing the functional symbol with all variables is greater than any other literal in the clause without functional

**Figure 3** The possible resolution inferences between clauses for the guarded fragment

	OF[1.3] : $l[\hat{c}] \vee p[\hat{c}]$ :1		OR[2.1.1; 2.1.2]: $\neg! \hat{g}[\bar{x}] \vee l[\hat{f}(\bar{x}), \bar{x}]$ :2
			OF[2.1.3] : $\neg! \hat{g}[\bar{x}] \vee l[\hat{f}(\bar{x}), \bar{x}] \vee p[\hat{f}(\bar{x}), \bar{x}]$ :2
		2.2	$\neg! \hat{g}[\bar{x}]^\# \vee l[\bar{x}]$
		2.2.1	$\neg! \hat{g}[\bar{x}] \vee l[\bar{x}]$ :OR.2
			OR[1.1; 2.2.1] : $l[\hat{c}]$ :1
			OR[2.1.1; 2.2.1]: $\neg! \hat{g}[\bar{x}] \vee l[\hat{f}(\bar{x}), \bar{x}]$ :2

subterms. This can be achieved by taking, say, any recursive path ordering  $\succ_{rpos}$  on expressions with the precedence  $>_P$  enjoying  $f >_P p$  for any functional symbol  $f$  and predicate symbol  $p$ . We define the selection function  $Sel$  for the clauses without functional symbols to select a negative literal containing all variables of the clause if there is one.

We prove that the clause class from (G) is closed under the ordered resolution by making case analysis of possible inferences between clauses of this class. The complete case analysis is given in Fig.3. The table is organized as follows. The clause schemes from (G) are spread in the table on different levels of precision. On the first level the schemes are given themselves. On the second level, different possibilities for eligible literals (marked by the asterisk) are considered. On the last level, possible inference rules that can be applied for a clause are identified and the expressions to be unified are underlined. For example, OR.1 marked to the right of the clause scheme 1.1 means that a clause represented by this scheme may act as a first premise of the ordered resolution rule. Below the last level, inferences between preceding clauses are drawn and their conclusions are identified as instances of clause schemes.

We have used the special form of literals in the clauses when the unifiers has been computed. For instance, the reason of why the resolution inference OR[2.1.1; 2.1.2] has produced the clause of the same depth is because the so-called *covering* expressions have been unified. An expression  $E$  is called *covering* if all functional subterms of  $E$  contain *all variables* of  $E$ . It is well known that the unifier for the two covering expressions maps the variables of the deepest expression to variables:

**Theorem 3.1 (Fermüller, Leitsch, Tammet & Zamov 1993)** *Let  $E_1$  and  $E_2$  be two covering expressions with  $dp(E_1) \geq dp(E_2)$  and let  $\sigma = mgu(E_1, E_2)$ . If  $\bar{x} = free(E_1)$  then  $\sigma$  maps  $\bar{x}$  to some vector of variables  $\bar{u}$ . As a conclusion  $dp(E_2\sigma) = dp(E_1\sigma) = dp(E_1)$ .*

**Theorem 3.2 (de Nivelles & de Rijke 2003)** *Ordered resolution decides the guarded fragment in double exponential time.*

*Proof.* Given a formula  $F \in \mathcal{GF}$  of the size  $n$ , the structural transformation introduces at most linear number of new predicate symbols with the arity not greater than  $n$ . Since every non-ground clause from (G) has a guard, the number of variables in such a clause does not exceed  $n$ . It can be shown that at most  $c = 2^{2^{O(n \log n)}}$  different clauses from (G) over the initial and introduced signature can be constructed. A saturation of the size  $c$  can be computed in time  $O(c^2)$ . So the resolution decision procedure for  $\mathcal{GF}$  can be implemented in 2EXPTIME.  $\square$

## 4 The Guarded Fragment With Transitivity

Some binary predicates of  $\Sigma$ , which we call *transitive predicates* have a *special* status. We usually denote them by the letters  $T, S$  and use the *infix* notation  $(t_1 T t_2)$  rather than the *postfix* notation  $a(t_1, t_2)$ , as for the other predicates. For any group of transitive predicates  $\hat{T} = \{T_1, \dots, T_n\}$ , the shortcuts  $(x\hat{T}y)$  and  $\neg(x\hat{T}y)$  represent respectively the disjunctions  $(xT_1y) \vee \dots \vee (xT_ny)$  and  $\neg(xT_1y) \vee \dots \vee \neg(xT_ny)$ . We assume that every set of clauses  $N$  contains the *transitivity clause*:  $\neg(xTy) \vee \neg(yTz) \vee xTz$  for every transitive predicate  $T$ .

The *guarded fragment with transitive guards*  $\mathcal{GF}[\mathcal{TG}]$  is defined by:

$$\mathcal{GF}[\mathcal{TG}] ::= \mathbf{A} \mid \mathbf{F}_1 \vee \mathbf{F}_2 \mid \mathbf{F}_1 \wedge \mathbf{F}_2 \mid \neg \mathbf{F}_1 \mid \forall \bar{x}.(\mathbf{G} \rightarrow \mathbf{F}_1) \mid \exists \bar{x}.(\mathbf{G} \wedge \mathbf{F}_1).$$

where  $\mathbf{F}_i, i = 1, 2$  are from  $\mathcal{GF}[\mathcal{TG}]$ ,  $\mathbf{A}$  is a non-transitive atom and  $\mathbf{G}$  is a (possibly transitive) guard for  $\mathbf{F}_1$ . Note that  $\mathcal{GF}$  can be seen as a subfragment of  $\mathcal{GF}[\mathcal{TG}]$ , when there are no transitive predicates. It is easy to see from the CNF transformation for guarded formulas that transitive predicates can appear only in initial clauses of the form:  $\neg xTy \vee l[x, y]$ ,  $\neg xTx \vee l[x]$  or  $\neg g(x) \vee T[x, f(x)]$ . We present a resolution decision procedure for  $\mathcal{GF}[\mathcal{TG}]$  as an extension of the one for  $\mathcal{GF}$  by carefully analyzing and blocking the cases when resolution with transitivity predicates can lead to unbounded generation of clauses.

**Figure 4** Resolution with the transitivity axiom may increase the size of clauses

1. $\neg(\underline{\mathbf{xTy}})^* \vee \neg(yTz) \vee xTz$ ;	1. $\neg(\underline{\mathbf{xTy}})^\# \vee \neg(\underline{\mathbf{yTz}})^\# \vee xTz$ ;

OR[2; 1]: 3. $\alpha(x) \vee \neg(xTz) \vee \underline{\mathbf{f(x)Tz}}^*$ ;	HR[2, 2; 1]: 3. $\alpha(x) \vee \underline{\mathbf{ff(x)Tx}}^*$ ;
OR[3; 1]: 4. $\alpha(x) \vee \neg(xTz) \vee \neg(zTz_1) \vee \underline{\mathbf{f(x)Tz_1}}^*$ ;	HR[3, 2; 1]: 4. $\alpha(x) \vee \underline{\mathbf{fff(x)Tx}}^*$ ;
.....: .....	.....: .....

#### 4.1 Obstacles for deciding the guarded fragment with transitivity

The transitivity clauses do not behave well when they resolve with each other because the number of variables increases. The simple solution is to block the inferences between the transitivity axioms by setting the selection function  $Sel$  such that it selects one of the negative literals. However this is only a partial solution to the problem since saturation with other clauses, in which positive transitive literals “should” be maximal, generate arbitrary large clauses as shown in the left part of Fig.4. The reason for the growth of the clause size is that the atoms which were resolved in the inferences *do not contain all variables* of the clause. To keep the number of variables from growing it is possible to use the *hyperresolution*, namely to select both negative literals of the transitivity clause and resolve them simultaneously. However, this strategy may result in increase of the clause depth, as shown in the right part of Fig.4. Note that the variable depth in hyperresolution inference with the transitivity clause grows only if for the terms  $h$ ,  $t$  and  $s$  which were simultaneously unified with  $x$ ,  $y$  and  $z$  respectively, either  $h \succ \max(t, s)$  or  $s \succ \max(t, h)$ . In all other cases, say, when  $h = t \succ s$  like in the inference below, neither variable depth nor the number of variables grows:

$$\begin{array}{l}
 1. \alpha(x) \vee \underline{\mathbf{xTx}}^*; \quad 2. \beta(x) \vee \underline{\mathbf{f(x)Tx}}^*; \quad 3. \neg(\underline{\mathbf{xTy}})^\# \vee \neg(\underline{\mathbf{yTz}})^\# \vee xTz; \\
 \text{HR}[1, 2; 3]: 4. \alpha(f(x)) \vee \beta(x) \vee f(x)Tx;
 \end{array}$$

We are going to distinguish these cases of using the transitivity clauses by using *ordering constraints* in combination with a selection function. We split the transitivity clause into the *constraint* clauses of the following forms:

$$\begin{array}{l}
 \text{T} \quad \frac{\neg(xTy) \vee \neg(yTz) \vee xTz}{\text{T.1. } \neg(\underline{\mathbf{xTy}})^\# \vee \neg(yTz) \vee xTz \mid x \succ \max(y, z);} \\
 \text{T.2. } \neg(xTy) \vee \neg(\underline{\mathbf{yTz}})^\# \vee xTz \mid z \succ \max(y, x); \\
 \text{T.3. } \neg(\underline{\mathbf{xTy}})^\# \vee \neg(\underline{\mathbf{yTx}})^\# \vee xTx \mid x \succ y; \\
 \text{T.4. } \neg(\underline{\mathbf{xTy}})^\# \vee \neg(\underline{\mathbf{yTz}})^\# \vee xTz \mid y \succeq \max(x, z);
 \end{array} \tag{T}$$

where selected literals are indicated with the asterisk. In the sequel, assume that every set of clauses contains transitivity clauses **T.1** – **T.4** from (T) for every transitive predicate  $T$ .

## 4.2 Redundancy of inferences involving transitive relations

In this section we prove the main technical lemmas that allow to gain a control over the saturation process in presence of transitivity clauses. We show that many inferences involving transitive predicates are redundant. The definition of redundancy for inferences is not very convenient to use. We proof auxiliary lemmas using which redundancy of inferences can be shown in a much simpler way.

**Lemma 4.1 (Four Clauses)** *Let  $N$  be a clause set containing the ground clauses:*

$$\mathbf{C1.} \ C \vee C' \vee \underline{\mathbf{A}}^*; \quad \mathbf{C2.} \ D \vee D' \vee \neg \underline{\mathbf{A}}^*; \quad \mathbf{C3.} \ C \vee D \vee B; \quad \mathbf{C4.} \ C' \vee D' \vee \neg B;$$

*Then the following ordered resolution inference:*

$$\text{OR}[\mathbf{C1}; \mathbf{C2}]: \text{P.} \quad C \vee C' \vee D \vee D'; \quad \text{is redundant provided that } A \succ B.$$

*Proof.* Obviously, the conclusion of the inference  $\text{OR}[\mathbf{C1}; \mathbf{C2}]$  follows from the clauses **C3** and **C4**. It remains to show that both **C3** and **C4** are smaller than the maximum of the clauses **C1** and **C2**. We use the fact that the conclusion of the ordered resolution inference is always smaller than the premise with the negative eligible literal. Therefore,  $C \vee D \prec \text{P} \prec \mathbf{C2}$  and since  $B \prec \neg A \prec \mathbf{C2}$ ,  $\mathbf{C3} = C \vee D \vee B \prec \mathbf{C2}$ . Similarly,  $\mathbf{C4} \prec \mathbf{C2}$ . We have shown that  $\max(\mathbf{C3}, \mathbf{C4}) \prec \max(\mathbf{C1}, \mathbf{C2})$ , thus the inference  $\text{OR}[\mathbf{C1}; \mathbf{C2}]$  is redundant.  $\square$

Lemma 4.1 can be generalized to show redundancy of hyperresolution inferences as follows:

**Lemma 4.2** *Let  $N$  be a clause set containing the ground clauses:*

$$\begin{aligned} \mathbf{C1.} \ C_1 \vee \underline{\mathbf{A}}_1^*; \quad \dots \quad \mathbf{Cn.} \ C_n \vee \underline{\mathbf{A}}_n^*; \quad \mathbf{D1.} \ C'_1 \vee D'_1; \quad \dots \quad \mathbf{Dm.} \ C'_m \vee D'_m; \\ \mathbf{C.} \ C \vee \neg \underline{\mathbf{A}}_1^\# \vee \dots \vee \neg \underline{\mathbf{A}}_n^\#; \end{aligned}$$

*for  $n, m > 1$  such that: (i)  $C_1 \vee \dots \vee C_n \vee C = C'_1 \vee \dots \vee C'_m$ , (ii)  $D'_1 \wedge \dots \wedge D'_m \models \perp$  and (iii)  $\max(A_1, \dots, A_n) \succ \max(D'_1, \dots, D'_m)$ . Then the (hyper-)resolution inference:*

$$\text{HR}[\mathbf{C1}, \mathbf{C2}, \dots, \mathbf{Cn}; \mathbf{C}]: \text{P.} \quad C_1 \vee C_2 \vee \dots \vee C_n \vee C; \quad \text{is redundant.}$$

*Proof.* The conclusion  $C_1 \vee \dots \vee C_n \vee C = C'_1 \vee \dots \vee C'_m$  of the inference logically follows from the clauses  $\mathbf{D1}, \dots, \mathbf{Dm}$  because of the condition (ii).

Moreover,  $\max(D1, \dots, Dm) \prec \max(C1, \dots, Cn, C) = C$  since for any  $i$  with  $1 \leq i \leq m$ ,  $C'_i \prec P \prec C$  (condition (i)) and  $D'_i \prec \neg A_1 \vee \dots \vee \neg A_n$  (condition (iii)). Therefore, the inference  $\text{HR}[C1, C2, \dots, Cn; C]$  is redundant.  $\square$

For proving redundancy of inferences involving transitive relations, we need to make additional assumption about the the ordering  $\succ$  used in  $\mathcal{OR}_{Sel}^\succ$ . We say that the ordering  $\succ$  is *T-argument monotone* if: **(i)**  $\{t_1, t_2\} \succ_{mul} \{s_1, s_2\}$  implies  $(t_1 T t_2) \succ (s_1 T s_2)$ , and **(ii)**  $b(t_1, t_2) \succ (t_1 T t_2) \succ u(t_1)$  for any non-transitive predicate  $b$  and unary predicate  $u$ . From now on we assume that the ordering  $\succ$  is T-argument monotone. The intended ordering can be easily obtained from the ordering  $\succ_{rpos}$ , that has been used for deciding the guarded fragment, by requiring that all transitive predicates have the multiset status and  $b \succ_P T \succ_P u$  for any non-transitive predicate  $b$  whose arity is greater than two, transitive predicate  $T$  and unary predicate  $u$ .

**Lemma 4.3** *Let  $N$  be a clause set containing the clause:*

1.  $C \vee \underline{\mathbf{t_1 T t_2^*}}$ ; together with the result of the inference:
  - (a)  $\text{HR}[1; \text{T.1}]: 2. C \vee \neg(t_2 T z) \vee \underline{\mathbf{t_1 T z^*}} \mid t_1 \succ \max(t_2, z)$ ; or
  - (b)  $\text{HR}[1; \text{T.2}]: 2. C \vee \neg(x T t_1) \vee \underline{\mathbf{x T t_2^*}} \mid t_2 \succ \max(t_1, x)$ ;

*Then the following inferences are redundant respectively:*

- (a)  $\text{HR}[2; \text{T.1}]: C \vee \neg(t_2 T z) \vee \neg(z T z_1) \vee t_1 T z_1 \mid t_1 \succ \max(t_2, z, z_1)$ ;
- (b)  $\text{HR}[2; \text{T.2}]: C \vee \neg(x_1 T x) \vee \neg(x T t_1) \vee x_1 T t_2 \mid t_2 \succ \max(t_1, x, x_1)$ .

*Proof.* **(a)** The result of any instance of the inference  $\text{HR}[2; \text{T.1}]$ :

- 2a.  $C \vee \neg(t_2 T s) \vee \underline{\mathbf{t_1 T s^*}} \mid t_1 \succ \max(t_2, s)$ ;
- T.1a.  $\neg(\underline{\mathbf{t_1 T s}})^\# \vee \neg(s T h) \vee t_1 T h \mid t_1 \succ \max(s, h)$ ;
- $\text{HR}[2a; \text{T.1a}]: C \vee \neg(t_2 T s) \vee \neg(s T h) \vee t_1 T h \mid t_1 \succ \max(t_2, s, h)$ ;

can be obtained from other instances of the constraint clauses 2 and T:

- 2b.  $C \vee \neg(t_2 T h) \vee t_1 T h \mid t_1 \succ \max(t_2, h)$ ;
- Tb.  $\neg(t_2 T s) \vee \neg(s T h) \vee \underline{\mathbf{t_2 T h}}$ ;

by resolving on the smaller atom:  $t_2 T h \prec t_1 T s$ . Therefore, by Lemma 4.1 the inference is redundant. The case **(b)** is proven symmetrically to **(a)**.

$\square$

**Lemma 4.4** *Let  $N$  be a clause set containing the clauses:*

1.  $C \vee \underline{\mathbf{t_1 T t_2^*}}$ ;
2.  $D \vee \underline{\mathbf{t_2 T t_3^*}}$ ;
- $\text{HR}[1; \text{T.2}]$  : 3.  $C \vee \neg(x T t_1) \vee \underline{\mathbf{x T t_2^*}} \mid t_2 \succ \max(t_1, x)$ ;
- $\text{HR}[2; \text{T.1}]$  : 4.  $D \vee \neg(t_3 T z) \vee \underline{\mathbf{t_2 T z^*}} \mid t_2 \succ \max(t_3, z)$ ;
- $\text{HR}[1, 2; \text{T.4}]$ : 5.  $C \vee D \vee t_1 T t_3 \mid t_2 \succeq \max(t_1, t_3)$ ;
- $\text{HR}[2, 3; \text{T.3}]$ : 6.  $D \vee C \vee \neg(t_3 T t_1) \vee t_2 T t_2 \mid t_2 \succ t_3$ ;

Then the following inferences are redundant:

- (a)  $\text{HR}[1, 4; \text{T.4}]: C \vee D \vee \neg(t_3Tz) \vee t_1Tz \mid t_2 \succ \max(t_3, z); t_2 \succeq t_1$
- (b)  $\text{HR}[3, 2; \text{T.4}]: C \vee D \vee \neg(xTt_1) \vee xTt_3 \mid t_2 \succ \max(t_1, x); t_2 \succeq t_3$
- (c)  $\text{HR}[3, 4; \text{T.4}]: C \vee D \vee \neg(xTt_1) \vee \neg(t_3Tz) \vee xTz \mid t_2 \succ \max(t_1, t_3, x, z);$
- (d)  $\text{HR}[4, 3; \text{T.3}]: D \vee C \vee \neg(t_3Tx) \vee \neg(xTt_1) \vee t_2Tt_2 \mid t_2 \succ \max(t_1, t_3, x).$

*Proof.* **(a)** The result of any instance of the inference  $\text{HR}[1, 4; \text{T.4}]$ :

- 1a.  $C \vee \underline{t_1Tt_2}^*$ ;
- 4a.  $D \vee \neg(t_3Ts) \vee \underline{t_2Ts}^* \mid t_2 \succ \max(t_3, s);$
- $\text{HR}[1a, 4a; \text{T.4}]: C \vee D \vee \neg(t_3Ts) \vee t_1Ts \mid t_2 \succ \max(t_3, s); t_2 \succeq t_1$

follows from the clause 5 and an instance of the transitivity clause:

- 5a.  $C \vee D \vee \underline{t_1Tt_3} \mid t_2 \succeq \max(t_1, t_3);$
- Ta.  $\neg(\underline{t_1Tt_3}) \vee \neg(t_3Ts) \vee t_1Ts;$

by resolving on  $t_1Tt_3 \prec t_1Tt_2$ . By Lemma 4.2, the inference is redundant.

**(b)** The case **(b)** is proven symmetrically to **(a)**.

**(c)** For any instance of the inference  $\text{HR}[3, 4; \text{T.3}]$  satisfying the constraints:

- 3b.  $C \vee \neg(hTt_1) \vee \underline{hTt_2}^* \mid t_2 \succ \max(t_1, h);$
- 4b.  $D \vee \neg(t_3Ts) \vee \underline{t_2Ts}^* \mid t_2 \succ \max(t_3, s);$
- $\text{HR}[3b, 4b; \text{T.4}]: C \vee D \vee \neg(hTt_1) \vee \neg(t_3Ts) \vee hTs \mid t_2 \succ \max(t_1, t_3, h, s);$

the conclusion follows from instances of the clause 5 and the transitivity clause:

- 5b.  $C \vee D \vee \underline{t_1Tt_3} \mid t_2 \succeq \max(t_1, t_3);$
- Tb.  $\neg(\underline{t_1Tt_3}) \vee \neg(t_3Ts) \vee \underline{t_1Ts};$
- Tb'.  $\neg(hTt_1) \vee \neg(\underline{t_1Ts}) \vee hTs;$

by resolving on  $t_1Tt_3$  and  $t_1Ts$ , each of them being smaller than both  $hTt_2$  and  $t_2Ts$ . Therefore the inference is also redundant by Lemma 4.2.

**(d)** For any instance of the inference  $\text{HR}[4, 3; \text{T.3}]$  satisfying the constraints:

- 4c.  $D \vee \neg(t_3Th) \vee \underline{t_2Th}^* \mid t_2 \succ \max(t_3, h);$
- 3c.  $C \vee \neg(hTt_1) \vee \underline{hTt_2}^* \mid t_2 \succ \max(t_1, h);$
- $\text{HR}[4, 3; \text{T.3}]: D \vee C \vee \neg(t_3Th) \vee \neg(hTt_1) \vee t_2Tt_2 \mid t_2 \succ \max(t_1, t_3, h).$

the conclusion follows from the clause 6 and the transitivity clause:

- 6c.  $D \vee C \vee \neg(t_3Tt_1) \vee t_2Tt_2 \mid t_2 \succ t_3;$
- Tc.  $\neg(t_3Th) \vee \neg(hTt_1) \vee \underline{t_3Tt_1};$

by resolving on  $t_3Tt_1$  which is smaller than any of the atoms  $t_2Ts$  and  $hTt_2$ . Therefore, the inference is redundant by Lemma 4.2.  $\square$

---

**Figure 5** A saturation inference producing a clause with more variables

---

1.  $\alpha(x) \vee \underline{\mathbf{f}(\mathbf{x})T\mathbf{x}^*}$ ;
  2.  $\neg(\underline{\mathbf{x}T\mathbf{y}})^\sharp \vee a(x) \vee \beta(y)$ ;
  3.  $\neg(\underline{\mathbf{x}T\mathbf{y}})^\sharp \vee \neg a(x) \vee \beta'(y)$ ;
  - HR[1; T.1]: 5.  $\alpha(x) \vee \neg(xTz) \vee \underline{\mathbf{f}(\mathbf{x})Tz^*} \mid f(x) \succeq \max(x, z)$ ;
  - HR[5; 2] : 6.  $\alpha(x) \vee \neg(xTz) \vee \underline{\mathbf{a}(\mathbf{f}(\mathbf{x}))^*} \vee \beta(z) \mid f(x) \succeq \max(x, z)$ ;
  - HR[5; 3] : 7.  $\alpha(x) \vee \neg(xTz_1) \vee \underline{\neg\mathbf{a}(\mathbf{f}(\mathbf{x}))^*} \vee \beta'(z_1) \mid f(x) \succeq \max(x, z_1)$ ;
  - OR[6; 7] : 8.  $\alpha(x) \vee \neg(xTz) \vee \neg(xTz_1) \vee \beta(z) \vee \beta'(z_1) \mid f(x) \succeq \max(x, z, z_1)$ ;
  - ..... : .....
- 

We have shown that redundancy and ordering constraints help to avoid many inferences involving transitivity. In particular the inference producing the clause 4 in the left part of Fig.4 can be shown to be redundant by Lemma 4.3. However, certain inferences may still result in increasing of the number of variables in clauses as in the situation shown on Fig.5. The problem here is that the functional term  $f(x)$  which does not contain all variables of the clause appears as an argument of a non-transitive predicate. That has happened as result of resolution inferences OR[5; 2] and OR[5; 3]. To resolve this problem we introduce an additional inference rule:

### Transitive Recursion

$$\text{TR} : \frac{\neg(\underline{\mathbf{x}\hat{T}\mathbf{y}})^\sharp \vee \alpha[x] \vee \beta[y]}{\begin{array}{l} \neg(\underline{\mathbf{x}\hat{T}\mathbf{y}}) \vee \alpha[x] \vee u_\alpha^{\hat{T}}(y) \\ \neg(\underline{\mathbf{x}\hat{T}\mathbf{y}}) \vee \neg u_\alpha^{\hat{T}}(x) \vee u_\alpha^{\hat{T}}(y) \\ \neg u_\alpha^{\hat{T}}(y) \vee \beta[y] \end{array}}$$

where (i)  $\hat{T}$  is a not empty set of transitive predicates (ii)  $u_\alpha^{\hat{T}}$  is a special unary predicate symbol indexed by  $\alpha$  and  $\hat{T}$ .

The inference rule extends the signature by introducing new unary predicate symbols  $u_\alpha^{\hat{T}}$ , whose intended interpretation is “the set of elements that are  $T$ -reachable from the ones where  $\alpha$  is false”.

**Lemma 4.5** *The transitive recursion rule is a sound inference rule.*

*Proof.* Let  $\mathcal{M}$  be a model for the premise of the rule, such that all predicates  $T_1, \dots, T_n$  from  $\hat{T}$  are interpreted by transitive relations and let  $xT'y := xT_1y \wedge \dots \wedge xT_ny$ . Obviously,  $T'$  is a transitive relation in  $\mathcal{M}$ . We extend  $\mathcal{M}$  to a model  $\mathcal{M}'$  by interpreting the new predicate  $u_\alpha^{\hat{T}}(x)$  as the formula  $\exists x'. (\neg\alpha(x') \wedge x'T'x)$ . In particular,  $\mathcal{M}' \models \forall y. ([\exists x. (\neg\alpha(x) \wedge xT'y)] \rightarrow u_\alpha^{\hat{T}}(y))$ ,

so the first conclusion of the inference rule is true in  $\mathcal{M}'$ . The following sequence of implications:  $u_{\alpha}^{\hat{T}}(x) \wedge xT'y \equiv \exists x'. [\neg\alpha(x') \wedge x'T'x \wedge xT'y] \Rightarrow$  (transitivity of  $T'$ )  $\Rightarrow \exists x'. [\neg\alpha(x') \wedge x'T'y] \equiv u_{\alpha}^{\hat{T}}(y)$  shows that the second conclusion is true in  $\mathcal{M}'$ . Finally, the last conclusion is a consequence of the premise of the rule:  $u_{\alpha}^{\hat{T}}(y) \equiv \exists x'. (\neg\alpha(x') \wedge x'T'y) \Rightarrow \exists x'. \beta(y) \equiv \beta(y)$ .  $\square$

Note that the transitive recursion rule is not a reduction rule, since the premise does not always follow from the conclusions when there are more than one transitive predicate. Even more, the inference may produce larger clauses, say, when  $\beta(y)$  is empty. However, the rule helps to avoid dangerous inferences involving transitive predicates, like in the example above, by making them redundant:

**Lemma 4.6** *Let  $\hat{T} = \{T_1, \dots, T_n\}$  with  $n \geq 1$  be a set of transitive predicates and  $N$  be a clause set containing the following clauses:*

$$\begin{aligned} D. \quad & \neg(\mathbf{x}\hat{\mathbf{T}}\mathbf{z})^{\sharp} \vee \alpha(x) \vee \beta(z); & D_3. \quad & \neg u(z) \vee \beta(z); \\ D_1. \quad & \neg(\mathbf{x}\hat{\mathbf{T}}\mathbf{z})^{\sharp} \vee \alpha(x) \vee u(z); & 1^i. \quad & C_i \vee \underline{\mathbf{tT}_i\mathbf{h}^*}, \quad 1 \leq i \leq n. \\ D_2. \quad & \neg(\mathbf{x}\hat{\mathbf{T}}\mathbf{z})^{\sharp} \vee \neg u(x) \vee u(z); & \text{HR}[1^1, \dots, 1^n; D_1]: 2. \quad & C_1 \mathbb{W} C_n \vee \alpha(t) \vee u(h). \end{aligned}$$

with the conclusions of the following inferences: either

$$\text{HR}[1^i; \text{T.1}]: 3_a^i. C_i \vee \neg(hT_i z) \vee \underline{\mathbf{tT}_i\mathbf{z}^*} \mid t \succ \max(h, z); \quad 1 \leq i \leq n.$$

or

$$\text{HR}[1^i; \text{T.2}]: 3_b^i. C_i \vee \neg(xT_i t) \vee \underline{\mathbf{xT}_i\mathbf{h}^*} \mid h \succ \max(t, x); \quad 1 \leq i \leq n.$$

Then the following inferences are redundant respectively:

$$\begin{aligned} \text{(a)} \quad & \text{HR}[3_a^1, \dots, 3_a^n; D]: \mathbb{W}_{i=1}^n \{C_i \vee \neg(hT_i z)\} \vee \alpha(t) \vee \beta(z) \\ \text{(b)} \quad & \text{HR}[3_b^1, \dots, 3_b^n; D]: \mathbb{W}_{i=1}^n \{C_i \vee \neg(xT_i t)\} \vee \alpha(x) \vee \beta(h) \end{aligned}$$

*Proof.* Consider the case (a) (case (b) is proven symmetrically). For any instance of the inference  $\text{HR}[3_a^1, \dots, 3_a^n; D]$  satisfying the constraints:

$$\begin{aligned} 3_a^i. \quad & C_i \vee \neg(hT_i s) \vee \underline{\mathbf{tT}_i\mathbf{s}^*} \mid t \succ \max(h, s); \\ D. \quad & \neg(\underline{\mathbf{tT}_i\mathbf{s}})^{\sharp} \vee \alpha(t) \vee \beta(s); \\ \text{HR}[3_a^1, \dots, 3_a^n; D]: \quad & \mathbb{W}_{i=1}^n \{C_i \vee \neg(hT_i s)\} \vee \alpha(t) \vee \beta(s) \end{aligned}$$

the conclusion can be derived from the clause 2 and instances of  $D_2$  and  $D_3$ :

$$\begin{aligned} 3. \quad & C_1 \mathbb{W} C_n \vee \alpha(t) \vee \underline{u(h)}. \\ D_2^a. \quad & \neg(\underline{h\hat{T}s}) \vee \underline{\neg u(h)} \vee \underline{u(s)}; \\ D_3^a. \quad & \underline{\neg u(s)} \vee \beta(s); \end{aligned}$$

by resolving on  $u(h)$  and  $u(s)$ , both of which are smaller than each  $tT_i s$  used in the inference. Therefore the inference is redundant by Lemma 4.2.  $\square$

**Remark 4.1** Note that the inferences  $\text{HR}[3_a^1, \dots, 3_a^n; D_1]$  and  $\text{HR}[3_a^1, \dots, 3_a^n; D_2]$  ( $\text{HR}[3_b^1, \dots, 3_b^n; D_1]$  and  $\text{HR}[3_b^1, \dots, 3_b^n; D_2]$ ) are redundant as well, since we can apply Lemma 4.6 for  $\beta(z) := u(z)$ ; and  $\alpha(x) := \neg u(x)$ ,  $\beta(z) := u(z)$  respectively (one should not use the clause  $D_3$  in this case).

### 4.3 Saturation of the clause set

We have prepared a ground for describing a resolution decision procedure for  $\mathcal{GF}[\mathcal{TG}]$ . However, to simplify the upcoming case analysis, we introduce an additional inference rule:

#### Literal Projection

$$\text{LP} : \frac{\llbracket C \vee L[!x]^\# \rrbracket}{C \vee p_{L[!]}(x) \vee \neg p_{L[!]}(x) \vee L[!x]}$$

where (i)  $L$  is non-unary literal with  $\text{free}[L]=\{x\}$ ; (ii)  $C$  contains  $x$  in non-unary literal or in functional subterm and (iii)  $p_L$  is a unary predicate for  $L$ .

The literal projection rule is a variant of the general splitting rule, which allows to split a clause by introducing a *new* predicate over shared variables of its parts. The purpose of this rule is to avoid clauses with several positive transitive literals that can be produced, for instance, with the inference:

$$\begin{array}{l} 1. \neg \mathbf{a}(\mathbf{f}(\mathbf{x}))^* \vee xT_1x; \quad 2. \neg b(x) \vee \mathbf{a}(\mathbf{f}(\mathbf{x}))^* \vee xT_2x; \\ \text{OR}[1; 2]: \neg b(x) \vee xT_1x \vee xT_2x; \end{array}$$

Instead of producing the inference above, one can alternatively simplify the clauses 1 and 2 using the literal projection rule and obtain a resolvent without transitive predicates.:

$$\begin{array}{l} 1a. p_{T_1}(x) \vee \neg \mathbf{a}(\mathbf{f}(\mathbf{x}))^* \quad 2a. p_{T_2}(x) \vee \neg b(x) \vee \mathbf{a}(\mathbf{f}(\mathbf{x}))^*; \\ 1b. \neg p_{T_1}(x) \vee xT_1x; \quad 2b. \neg p_{T_2}(x) \vee xT_2x; \\ \text{OR}[1a; 2a]: p_{T_1}(x) \vee p_{T_2}(x) \vee \neg b(x); \end{array}$$

Note that the literal projection rule cannot be applied to literals containing new predicate symbols since they are unary, therefore, only finitely many predicates  $p_L$  can be introduced.

We show the decidability of  $\mathcal{GF}[\mathcal{TG}]$  in similar way as for  $\mathcal{GF}$  by describing a clause class containing the input clauses for  $\mathcal{GF}[\mathcal{TG}]$ -formulae and closed under the ordered resolution inferences up to redundancy. This clause

class is represented by the set of the clause schemes below:

$$\begin{array}{ll}
1: & \langle \neg\hat{T}, \hat{\gamma} \rangle[\hat{c}]; & \hat{\alpha} := \{\hat{a}, \neg\hat{a}\}; \\
2: & \langle \neg\hat{d}, \hat{\gamma} \rangle[\hat{x}] \vee \langle \neg\hat{T}, \hat{\gamma} \rangle[\hat{!}f(\bar{x}), \bar{x}] \vee \hat{\beta}[f(\bar{x}), \bar{x}]; & \hat{\mathcal{T}} := \{\hat{T}, \neg\hat{T}\}; \\
3: & \neg\hat{p}^1(\hat{x}) \vee \neg\hat{p}^1(f(x)) \vee \hat{T}[f(x), x]; & \hat{b} := \{\hat{a}, p_{\hat{\alpha}}, p_{\hat{T}(\cdot)}\}; \\
\mathbf{T}: & \neg(xTy) \vee \neg(yTz) \vee xTz; & \hat{\beta} := \{\hat{b}, \neg\hat{b}\}; \\
4: & \neg\hat{p}^1(x) \vee \neg(xTz) \vee f(x)Tz \mid f(x) \succ z; & \hat{p} := \{\hat{b}, u_{\hat{\beta}}^{\tau}\}; \hat{\gamma} := \{\hat{p}, \neg\hat{p}\}; \\
5: & \neg\hat{p}^1(x) \vee \neg(zTx) \vee zTf(x) \mid f(x) \succ z; & \hat{d} := \{\hat{p}, \hat{T}\}; \hat{\delta} := \{\hat{d}, \neg\hat{d}\}. \\
\mathbf{R}: & \neg(x\hat{T}y) \vee \hat{\gamma}(x) \vee \hat{\gamma}(y); & 
\end{array} \tag{GT}$$

In the clause schemes we have used several auxiliary predicate and literal groups. The groups  $\hat{a}$  and  $\hat{T}$  consist of initial non-transitive and transitive predicate symbols respectively. The literal groups  $\hat{\alpha}$  and  $\hat{\mathcal{T}}$  are constructed from  $\hat{a}$  and  $\hat{T}$ . The predicate group  $\hat{b}$  consists of predicate symbols from  $\hat{a}$  in addition with predicate symbols introduced by the literal projection rule for the literals formed from  $\hat{\alpha}$  or  $\hat{\mathcal{T}}$ . The literal group constructed from these predicates is denoted by  $\hat{\beta}$ . The predicate group  $\hat{p}$  extends the group  $\hat{b}$  with predicate symbols introduced by the transitive recursion rule for the clauses formed from  $\hat{\beta}$ . Finally, the group  $\hat{d}$  consists of all previously mentioned predicate symbols. The groups  $\hat{\gamma}$  and  $\hat{\delta}$  are the literal groups for  $\hat{p}$  and  $\hat{d}$  respectively.

To make the scheme notation even more compact, we enclose several literal groups in brackets:  $\langle \neg\hat{T}, \hat{\gamma} \rangle(\hat{c})$  represents  $\neg\hat{T}(\hat{c}) \vee \hat{\gamma}(\hat{c})$ ; we use parameters for predicate and functional symbols to indicate that all occurrences of such symbols are the same within a clause, thus the scheme  $\mathbf{T}$  represents the transitivity axioms only; we use the infix notation for  $T$  and  $\hat{T}$  to indicate its “right” and “left” arguments, thus  $xTx$  can be represented by  $\hat{T}(x, y)$  but not by  $x\hat{T}y$ ; finally,  $\hat{p}^1$  denotes the subgroup of *unary* predicate symbols from  $\hat{p}$ .

The clause class can be described as follows. Clauses for the scheme 1 contain only constants as arguments and may contain transitive predicates only negatively. Clauses of the form 2 also contain transitive predicates negatively, have a negative atom containing all variables and all predicates introduced by the transitive recursion rule as well as all transitive predicates should contain all variables. Clauses of the form 3 originate from the clauses having positive occurrences of transitive predicates. They contain only one variable and have the same functional symbol everywhere.  $\mathbf{T}$  stands for transitivity axioms. Clauses of the form 4 and 5 are the only non-covering clauses which may appear in a saturation. The redundancy lemmas that we have proved aim for these clauses. And, finally, the clauses  $R$ , originated from the clauses with transitive guards, appear from the transitive recursion inference rule.

The complete case analysis showing the closure of the fragment from (GT) under  $\mathcal{OR}_{sel}^\succ$  with additional inferences is given in Appendix A. This proves the following theorem:

**Theorem 4.7** *There is a strategy based on  $\mathcal{OR}_{sel}^\succ$  with ordering constraints and additional inference rules such that given a formula  $F \in \mathcal{GF}[\mathcal{TG}]$  a finite clause set  $N$  containing the CNF transformation for  $F$  is produced such that: (i)  $N$  is closed under rules of  $\mathcal{OR}_{sel}^\succ$  up to redundancy and (ii)  $N$  is a subset of (GT).*

**Corollary 4.8 (Szwast & Tendera 2001)**  *$\mathcal{GF}[\mathcal{TG}]$  is decidable in double exponential time.*

*Proof.* Given a formula  $F \in \mathcal{GF}[\mathcal{TG}]$ , it could be seen from construction of (GT) that clauses generated in the saturation for  $F$  contain at most linear number of initial predicate and functional symbols and at most exponential number of introduced (by inferences extending the signature) *unary* predicates. Simple calculations show that the number of clauses from (GT) that can be constructed from them is at most double exponential. Therefore the saturation can be computed in double exponential time.  $\square$

## 5 Conclusions and future work

The resolution decision procedure for  $\mathcal{GF}[\mathcal{TG}]$  presented in the paper can shed light on the reasons why this fragment is so fragile with respect to decidability and which decidable extensions it may have. Note, that we in fact have already shown the decidability of a larger fragment: it is possible to admit non-empty *conjunctions* of transitive relations  $x\hat{T}y$  as guards since the CNF-transformation maps them to the same decidable fragment. This might help to find a decidable counterpart for the *interval-based* temporal logics à-la Halpern Shoham (Halpern & Shoham 1986) because the relation between intervals can be expressed as a conjunction of (transitive) relations between their endpoints.

Despite the fact that the fragment  $\mathcal{GF}[\mathcal{TG}]$  has a relatively high complexity: it is 2EXPTIME complete even for the case of monadic- $\mathcal{GF}[\mathcal{TG}]$  (Kieroński 2003), there are indications that this complexity will be not exhibited in our procedure for average problems. The saturation size explodes only when there are many clauses generated that are of the specific form for which the transitive recursion rule applies. In fact, our procedure can be shown to be in EXPTIME for the restricted version of  $\mathcal{GF}[\mathcal{TG}]$  that captures the description logic *SHI*. *SHI* is an extension of the basic description logic

$\mathcal{ALC}$  with inverse roles, transitive predicates and role hierarchies. For this fragment one can show that at most linear number of new predicate symbols can be introduced by the transitive recursion inference rule.

As a future work, we try to extend our approach to the case with equality, as well as to other theories like theories of associative compositional axioms:  $\forall xyz.(xSy \wedge yTz \rightarrow xHz)$  and theories of linear, branching and dense partial orderings without endpoints.

## Appendix A

### Saturation of the clause class (GT)

This appendix contains the case analysis of possible inferences between the clauses from (GT). The inferences are drawn in the system  $\mathcal{OR}_{Sel}^{\checkmark}$  with an addition of literal projection and transitive recursion inference rules and based on the ordering given in Section 4.2 and the selection function for transitivity axioms as given in (T) and for other clauses as defined in Section 3.2.

Below you find a list of the most recent technical reports of the Max-Planck-Institut für Informatik. They are available by anonymous ftp from [ftp.mpi-sb.mpg.de](ftp://ftp.mpi-sb.mpg.de) under the directory `pub/papers/reports`. Most of the reports are also accessible via WWW using the URL <http://www.mpi-sb.mpg.de>. If you have any questions concerning ftp or WWW access, please contact [reports@mpi-sb.mpg.de](mailto:reports@mpi-sb.mpg.de). Paper copies (which are not necessarily free of charge) can be ordered either by regular mail or by e-mail at the address below.
